

THE SYSTEM IN THE COUNTRY I WANT TO ESTABLISH

I will establish my own country by piling up sand in a suitable place, like in the picture above.

Generating electricity on the coast using turbines heated by simple solar lenses—and storing enough power for a week in barrels of salt pulverized to a flour-like consistency (as shown in the image above) for use at night—is the most cost-effective method of electricity generation for regions with high solar exposure. In this way, 200 turbines and the salt barrels needed to store the generated electricity can be installed for 50 million dollars.

If there is not excessive sunlight, a system could be set up in a suitable coastal location—like the one shown in the image—where seawater is heated using solar concentrators to generate electricity; this electricity would then be used to cool the water and pump it into a reservoir. Once the reservoir is full, the pressurized water would drive turbines to generate electricity again. A portion of this generated power would be used to transfer water accumulating in a forebay back into the reservoir, while the remainder would serve as usable electricity for consumption.

Oil, fodder, and sugar can be produced by planting trees on hilly pasture or woodland areas—such as those shown in the image above—including walnut, hazelnut, almond, oak, chestnut, linden, and stone pine for oil and fodder, and carob, apple, pear, grape, and mulberry for sugar.

Walnut	4–6 years (grafted)	60–300+ years
Hazelnut	3–6 years	80–150+ years
Almond	2–4 years	40–50+ years
Oak	Around 20–40 years	200–1,000+ years
Chestnut	3–8 years	200–500+ years
Linden	10+ years	300–1,000+ years

Pine nut (pine nut)	8–15+ years	100–500+ years
Carob	6–8 years (grafted)	100–200+ years
Apple	2–5 years	50–150+ years
Pear	4–6 years	100–200+ years
Grape (vine)	2–4 years	40–100+ years
Mulberry	2–4 years	100–300+ years

Silk can be produced using silkworms on mulberry trees, as shown in the image above. Since only a portion of the tree's leaves is used, mulberry yield is not affected.

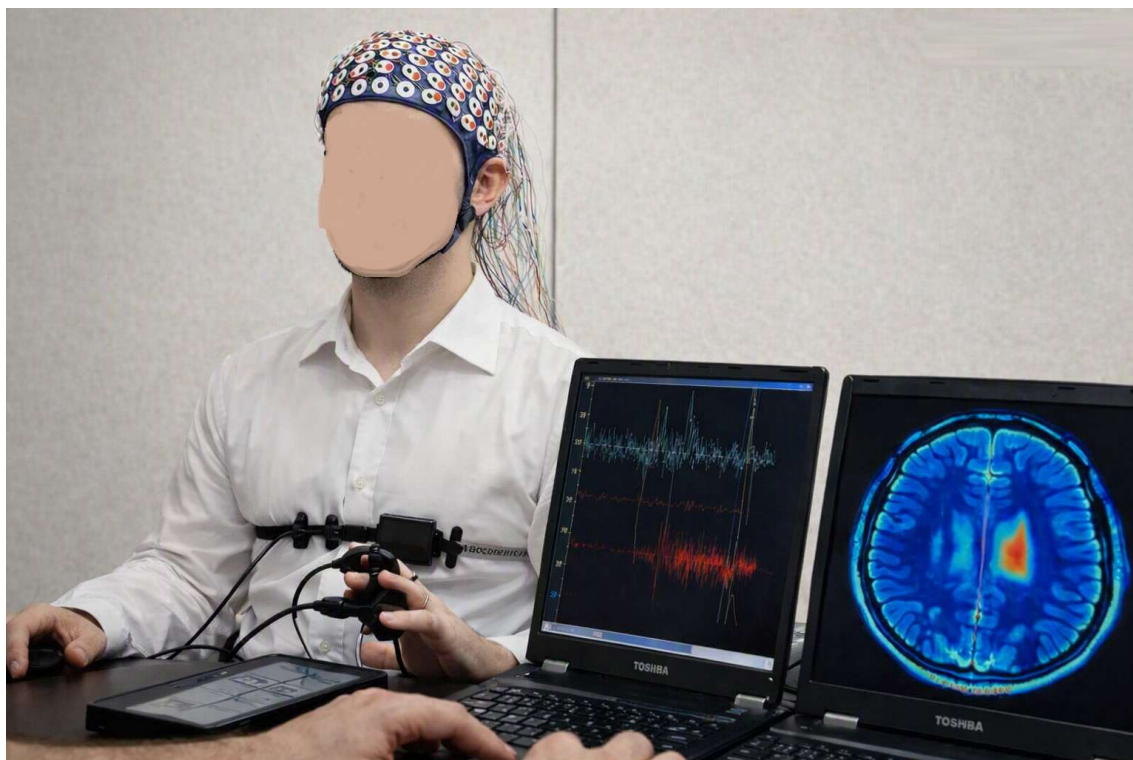

If cattle—like those in the picture above—are raised under a single cooperative umbrella, as few as five people can look after 1,000 head of cattle. Caring for cattle is demanding, whereas tending to sheep is easier, and they also produce wool.

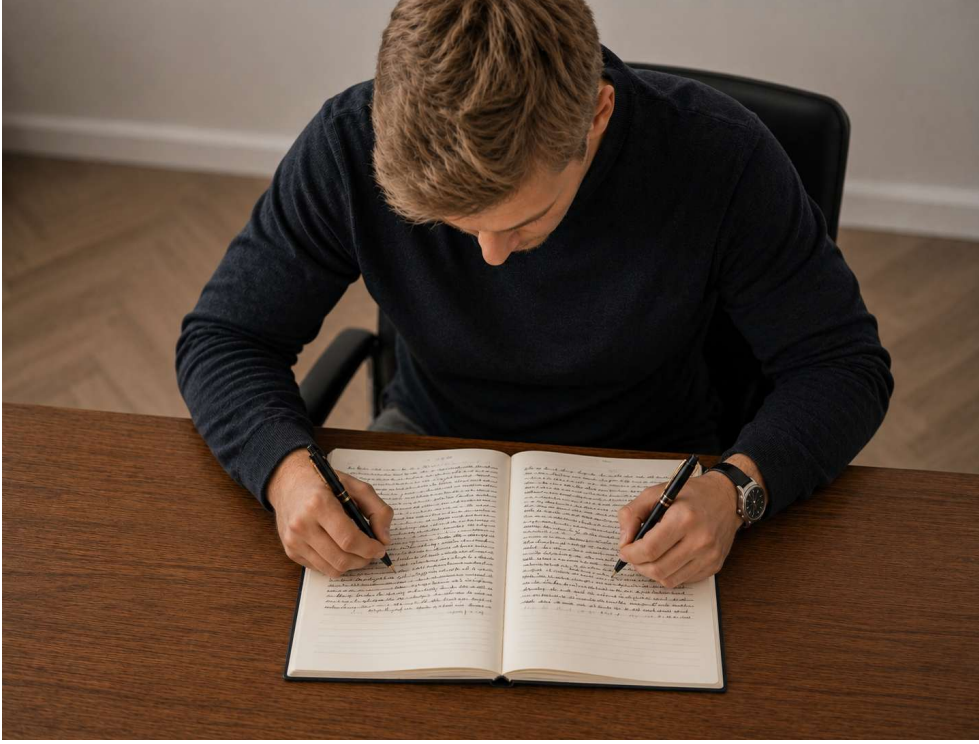

The wool and old garments shown in the images above can be processed into a powder form and then—by heating and applying high pressure, as illustrated in the image below—spun into threads as fine as cotton.

In interrogations like the one above, cases are resolved much more easily with the use of a lie detector and a brain-neuron connection machine.

If 666 positive attributes—like the ones mentioned above—are taught in schools and students are made to write them down, their consciousness will become positive, and they will have no desire to commit crimes.

I want to live in a country like that. And the easiest way is to establish my own country. I will have ample resources from the projects in my previous file. I will both provide advanced technology to my species and found my own nation. I will collaborate with the advanced countries—the ones shown in the cocktail image from the previous files—that deserve this technology. If you look at the IQ map, they are all countries with high IQ levels.
